

## Characterization

**Solar cell/modules characterization**

- Spectral response
- IV curve

**Other relevant tests**

- Degradation/ageing
- Reflectance
- Lifetime
- Infrared mapping

---

---

---

---

---

---

---

---

## Characterization

Solar cell/modules characterization

- **Spectral response**

---

---

---

---

---

---

---

---

## Characterization

Solar cell/modules characterization

- **Spectral response (SR)** is the short circuit current produced by the cell when illuminated by a given power
- **External quantum efficiency (EQE)** is the probability of an incident photon contributing to one electron to the short circuit current
- **Internal quantum efficiency (IQE)** is the probability of an absorbed photon contributing to one electron to the short circuit current

$$SR(\lambda) = \frac{I_{sc}}{P_{in}} \quad SR(\lambda) = \frac{q\lambda}{hc} EQE \quad IQE = \frac{EQE}{1 - R(\lambda)}$$

---

---

---

---

---

---

### Characterization

Solar cell/modules characterization

- Spectral response

**Determination of diffusion length:**  
 if  $\alpha^{-1} \ll t$  and  $L \ll t$  then, it can be shown that, for 800-1100nm:

$$\frac{1}{IQE} = 1 + \frac{1}{\alpha L}$$

and thus  $L$  can be extracted from plot  $IQE$  vs  $\alpha^{-1}$

H. Mackel, Capturing the spectra of solar cells, PhD Thesis, Australian National University, 2004

### Characterization

Solar cell/modules characterization

- IV curve

The diagram shows a solar cell under test with incident radiation. Below it is a graph of Spectral Irradiance (W/m²/nm) vs Wavelength (nm) from 200 to 1400 nm. The graph shows three curves: Air Mass 1.5G (red), 120 V ELH (green), and Arc Lamp (blue). The Air Mass 1.5G curve is the most uniform, while the 120 V ELH and Arc Lamp curves show significant peaks and troughs, particularly in the 400-800 nm range.

---

---

---

---

---

---

---

---

### Characterization

Solar cell/modules characterization

- IV curve: use **calibration cell** with same spectral response

or, if one knows spectral response of sample and reference cell and spectral irradiance of solar simulator, one may calculate the mismatch error:

- C.H. Seaman, *Calibration of Solar Cells by the Reference Cell Method - The Spectral Mismatch Problem*, Solar Energy, vol. 29, No. 4, 1982, pp. 291-298

---

### Characterization

Solar cell/modules characterization

- Reflectance

Light source

Mono-chromator

Chopper

Sample

Lock-in

Calibration using

- Aluminium sample (high reflectivity)
- 'Zero' background (low reflectivity)

---

---

---

---

---

---

---

---

### Characterization

Solar cell/modules characterization

- Reflectance

Figure 4: Reflectivity spectra of a macroporous texturised POLIX wafer (straight lines). For comparison the reflectivity curve of NaOH texturised, (100) oriented c-Si is also shown (◆).

S. Lust, et al. Mono and multicrystalline silicon solar cells based on macroporous silicon, Proc. of the 17<sup>th</sup> EPVSEC, Munich 2001

---

---

---

---

---

### Characterization

Solar cell/modules characterization

- Lifetime

Most common technique: MicroWave PhotoConductance Decay

Excess carriers generated by light pulse

Monitoring variation of microwave reflectivity

Calculation of lifetime from decay time constant

Figure 1.3: A typical inductively-coupled photo-conductance decay (PCD) trace for a 0.1Ω-cm FZ wafer showing the sharp illumination peak and the ensuing carrier decay. The calculated effective lifetimes for this trace are shown in Figure 1.6.

D.M. Macdonald, Recombination and trapping in multicrystalline silicon solar cells, PhD Thesis, Australian National University, 2001

## Characterization

Solar cell/modules characterization

- Lifetime

Critical issue for lifetime measurements: **surface passivation**

May be achieved by many different approaches:

- Growth deposition of a **dielectric film** or pn junction (e.g. a-Si)
- **Corona discharge** on SiO<sub>2</sub> film
- Immersion in hydrofluoric acid (HF)
- or alcoholic **iodine** solution

Figure 11: The effect of surface passivation on the lifetime of silicon solar cells. The lifetime of the cells is measured by the microwave photoconductivity decay method. The lifetime of the cells is measured by the microwave photoconductivity decay method. The lifetime of the cells is measured by the microwave photoconductivity decay method.

## Characterization

Solar cell/modules characterization

- **INFRARED IMAGING**

Includes

- Electroluminescence (EL)
- photoluminescence (PL) and
- lock-in thermography (LIT).

Allows measurement of

- Series or shunt resistance
- Junction breakdown
- Hot spots
- Lifetime

Kasemann et al. Progress in silicon solar cell characterization with infrared imaging methods. Proc. of the 23<sup>rd</sup> EPVSEC, Valencia 2008

---

---

---

---

---

---

---

---

---

## Characterization

### INFRARED IMAGING SETUP.

- Homogeneous irradiation of the entire solar cell is typically performed with lasers in the wavelength range from 790nm to 940nm. Different cameras can be used to detect radiation in different wavelength ranges.
- Spectral range of photon emission from silicon solar cells, the underlying mechanisms, and the detectors used.

**LAB ASSIGNMENT**

**Characterization** of one solar cell using:

- Spectral response measurement
- IV curve measurement

**Deliverable:**

- Report results in a paper format (chck template)
- Solar cell parameters:  $I_{sc}$ ,  $V_{oc}$ ,  $P_{max}$ ,  $\text{eff}$ ,  $R_s$ ,  $R_{sh}$ , ... and lifetime
- Discuss cell results
- Compare SR and IV measurement
